

Description

[LIGHT GUIDE PLATE STRUCTURE AND BACK LIGHT MODULE]

BACKGROUND OF INVENTION

[0001] Field of the Invention

[0002] The present invention relates to a light guide plate structure and a back light module, and more particularly to a light guide plate structure for improving scattering effects on a light scattering surface and a back light module applied therefrom.

[0003] Description of the Related Art

[0004] For the trend of small sizes of electronic products, the development of electronic devices is toward high density and integrity in small size electronic products. Because a variety of functions embodied within electronic products with small sizes, a large number of portable devices have been popularly used and replaced the big sized electronic products. Therefore, they have become the main stream in

consumer market. These portable devices includes, such as notebooks, cell phones, electronic dictionaries, personal digital assistants, web pads, tablet PC and portable games.

[0005] For the application of small size electronic products, liquid crystal displays (LCD) with high efficiency of space, high quality, low power consumption and low or no radiation have been popularly used. LCD is composed of a liquid crystal panel and a back light module. Because liquid crystal within the panel does not illuminate itself, the back light modules must provide a plate light source for the panel. Then, LCD serves the function of display. Therefore, back light modules are very important in displays.

[0006] FIG. 1 is a cross-sectional schematic drawing showing a prior art back light module. Referring to FIG. 1, the back light module 100 includes a light guide plate 110, a liner light source 120 and a reflective cover 130. The light guide plate 110 is, for example, a plate-type light guide plate, which comprises at least one light incident surface 112, a light scattering surface 114 and a light emitting surface 116. The light incident surface 112 is on a side-wall of the light guide plate 110, the light scattering surface 114 is on a bottom surface of the light guide plate

110 and the light emitting surface 116 is on a top surface of the light guide plate 110.

[0007] The liner light source 120 is, for example, a cold cathode florescent lamp, which is disposed next to the light incident surface 112 of the light guide plate 110, wherein light from the liner light source 120 transmits through the light incident surface 112 and enters into the light guide plate 110, and the light scattering surface 114 passes the light to the light emitting surfaces 116 and out thereof.

[0008] Additionally, the reflective cover 130 is disposed next to the light incident surface 112 of the light guide plate 110 and covers the liner light source 120 for reflecting light from the liner light source 120 to the light incident surface 112 of the light guide plate 110.

[0009] Referring to FIG. 1, the light scattering surface 114 of the light guide plate 110 provides a enough scattering area. Therefore, light from the liner light source 120 after being scattered on the light scattering surface 114 can uniformly travel to the light emitting surface 116, and the light exiting from the light emitting surface 116 transforms into a plate light source. It should be noted that a plurality of transparent bumps 140 are disposed on the light scattering surface 114 as scattering spots thereof in

prior art. The transparent bumps 140, however, are made of the same material of the light guide plate 110 and have the same refractive index as the light guide plate 110. Therefore, the scattering effect on the light scattering surface is limited.

[0010] FIG. 2 is a cross-sectional schematic drawing showing a prior art back light module. Referring to FIG. 2, a back light module 100' has the same structure as the back light module 100 described in FIG. 1. The same descriptions will not be repeated herein. The difference between these two back light modules is that a plurality of holes 150 are formed on the light scattering surface 114' serving as scattering spots thereon. However, in the prior art back light module light still transports in the same material. Therefore, the scattering effect on the light scattering surface 114' is limited.

[0011] From the descriptions mentioned, the prior art back light module by forming either transparent bumps or holes on the light scattering surface of the light guide plate cannot provide excellent scattering effect and a uniform plate light source because of back scattering effects thereon.

SUMMARY OF INVENTION

[0012] In an embodiment of the present invention, a of a light

guide plate structure, having a plurality of notches on a light scattering surface and disposing a plurality of transparent elements therein, is provided to improve the scattering effect thereof, wherein the refractive index of the plurality of transparent elements is different from that of the plurality of the light guide plate.

[0013] In an embodiment of the present invention, a back light module is provided to generate a better scattering effect on a scattering light surface and a plurality of notches are formed on the light scattering surface of the light guide plate and a plurality of transparent elements are disposed therein to provide a more uniform plate light source, wherein the refractive index of the plurality of transparent elements is different from that of the plurality of the light guide plate.

[0014] Accordingly, the present invention provides a light guide plate structure applied to a back light module and adapted to transform a linear light source into a plate light source. The guide light source structure comprises a light guide plate and a plurality of transparent elements. The light guide plate comprises at least one light incident surface, light scattering surface and a light emitting surface. The light incident surface is on a sidewall of the light

guide plate, the light scattering surface is on a bottom surface of the light guide plate and the light emitting surface is on a top surface of the light guide plate, wherein the light scattering surface has a plurality of notches. The plurality of transparent elements are disposed within the plurality of notches and a reflective index of the plurality of transparent elements is different from that of the light guide plate.

[0015] The present invention provides a back light module adapted to provide a plate light source. The back light module comprises a light guide plate structure and a liner light source. The guide light source structure comprises a light guide plate and a plurality of transparent elements. The light guide plate comprises at least one light incident surface, light scattering surface and a light emitting surface. The light incident surface is on a sidewall of the light guide plate, the light scattering surface is on a bottom surface of the light guide plate and the light emitting surface is on a top surface of the light guide plate, wherein the light scattering surface has a plurality of notches. The plurality of transparent elements is disposed within the plurality of notches and a reflective index of the plurality of transparent elements is different from that of the light

guide plate. The liner light source is next to the light incident surface of the light guide plate, wherein light from the liner light source transports the light incident surface and enters into the light guide plate, and the light scattering surface passes the light to the light emitting surfaces and out thereof.

[0016] In preferred embodiments of the present invention, these transparent elements are made of transparent material, such as glass or acrylic. In addition, the light guide plate is a plate-type light guide plate or a mesa light guide plate. When the light plate is a mesa light guide plate, the plurality of transparent elements have different sizes, the plurality of transparent elements are disposed on the light scattering surface in sequence by the size thereof, and bottom surfaces of the plurality of transparent elements are substantially on a same surface. Therefore, the mesa light guide plate can be firmly disposed on a plastic frame. Moreover, the liner light source is, for example, a cold cathode florescent lamp.

[0017] In preferred embodiments of the present invention, the back light module further comprises a reflective cover, which is disposed next to the light incident surface of the light guide plate and covers the liner light source for re-

flecting light from the liner light source to the light incident surface of the light guide plate. In order to improve luminance of the back light module, a diffusion sheet and a brightness enhancement film can be applied thereto. In the embodiment, the diffusion sheet can be disposed, for example, on the light emitting surface of the light guide plate, and the brightness enhancement film can be disposed on the diffusion sheet.

[0018] In the present invention, the plurality of notches are formed on the light scattering surface of the light guide plate and the plurality of transparent elements are disposed within the notches. In addition, the refractive index of these transparent elements is different from that of the light guide plate. When light comes into and goes out these transparent elements through the light guide plate, a better scattering effect is achieved and the back light module of the present invention provides a more uniform plate light source because of the refractive index difference between these transparent elements and the light guide plate.

[0019] In order to make the aforementioned and other objects, features and advantages of the present invention understandable, a preferred embodiment accompanied with fig-

ures is described in detail below.

BRIEF DESCRIPTION OF DRAWINGS

[0020] FIG. 1 is a cross-sectional schematic drawing showing a prior art back light module.

[0021] FIG. 2 is a cross-sectional schematic drawing showing a prior art back light module.

[0022] FIG. 3 is a cross-sectional schematic drawing showing a first preferred back light module in accordance with the present invention.

[0023] FIG. 4 is a cross-sectional schematic drawing showing a second preferred back light module in accordance with the present invention.

DETAILED DESCRIPTION

[0024] FIG. 3 is a cross-sectional schematic drawing showing a first preferred back light module in accordance with the present invention. Please referring to FIG. 3, the back light module 200 comprises a light guide plate structure 300 and a liner light source 210. The light guide plate structure 300 is composed of a light guide plate 310 and a plurality of transparent elements 312. The light guide plate 310 is, for example, a plate-type light guide plate, which comprises at least one light incident surface 312,

light scattering surface 314 and light emitting surface 316. The light incident surface 312 is on a sidewall of the light guide plate 310, the light scattering surface 314 is on a bottom surface of the light guide plate 310 and the light emitting surface 316 is on a top surface of the light guide plate 310, wherein the light scattering surface 314 has a plurality of notches 318.

[0025] The plurality of transparent elements 320 are made of transparent material, such as glass or acrylic, which are separately disposed within the plurality of notches 318 as scattering spots of the light scattering surface 314. Moreover, a reflective index of the plurality of transparent elements 320 is different from that of the light guide plate 310.

[0026] The liner light source 210 is, for example, a cold cathode florescent lamp, which is disposed next to the light incident surface 312 of the light guide plate 310, wherein light from the liner light source 210 transmits through the light incident surface 312 and enters into the light guide plate 310, and the light scattering surface 314 passes the light to the light emitting surfaces 316 and out thereof.

[0027] In addition, the back light module 200 further comprises a reflective cover 220, which is disposed next to the light

incident surface 312 of the light guide plate 310 and covers the liner light source 210 for reflecting light from the liner light source to the light incident surface 312 of the light guide plate 310. In order to improve luminance of the back light module 200, a diffusion sheet 230 and a brightness enhancement film 240 can be applied thereto. In the embodiment, the diffusion sheet 230 can be disposed, for example, on the light emitting surface 316 of the light guide plate 310, and the brightness enhancement film 240 can be disposed on the diffusion sheet 230.

[0028] It is to be noted that the plurality of notches 318 are formed on the light scattering surface 314 of the light guide plate 310 and the plurality of transparent elements 320 are disposed within the notches 318. In addition, the refractive index of these transparent elements 320 is different that of the light guide plate 310. When light comes into and goes out these transparent elements 320 through the light guide plate 310, a better scattering effect is achieved and the back light module 200 of the present invention provides a more uniform plate light source because of the refractive index difference between these transparent elements 320 and the light guide plate

310.

[0029] FIG. 4 is a cross-sectional schematic drawing showing a second preferred back light module in accordance with the present invention. A back light module 200' has the same structure as the back light module 200 described in the first preferred embodiment. The same descriptions will not be repeated. The difference between the first and the second embodiments is that the light guide plate 310' is, for example, a mesa light guide plate. The plurality of transparent elements 320' have different sizes, the plurality of transparent elements 320' are disposed into the notches 318' on the light scattering surface 314' in sequence by the size thereof, and bottom surfaces of the plurality of transparent elements 320' are substantially on a same surface. Therefore, the mesa light guide plate can be firmly disposed on a plastic frame (not shown) for improving the convenience of assembling the back light module.

[0030] From the descriptions mentioned above, in the present invention the plurality of notches are formed on the light scattering surface of the light guide plate and the plurality of transparent elements are disposed within the notches for serving as scattering spots on the light scattering sur-

face. In addition, the refractive index of these transparent elements is different that of the light guide plate. When light comes into and goes out these transparent elements through the light guide plate, a better scattering effect is achieved and the back light module of the present invention provides a more uniform plate light source because of the refractive index difference between these transparent elements and the light guide plate.

[0031] Although the present invention has been described in terms of exemplary embodiments, it is not limited thereto. Rather, the appended claims should be constructed broadly to include other variants and embodiments of the invention which may be made by those skilled in the field of this art without departing from the scope and range of equivalents of the invention.
